

IDEA

Collecting data available from NASA.

Processing it using Python libraries.

Then **analyzing** the data using AI models with a focus on identifying the relationship between environmental variables and potential risks.

Presenting the results: The results will be displayed on maps using libraries like Folium or Plotly. The maps will allow users to input their location, and areas with high risks will be shown based on the available data. For example, risk analysis related to floods or droughts in a specific area will be displayed based on the latest data.

User interaction: The tool will be user-friendly and allow users to input their geographic location. It will then display potential risks along with recommendations on actions that can be taken to mitigate these risks.

Tools and technologies used:

- Python for programming and data processing.
- Machine Learning for data analysis.
- Folium/Plotly for designing maps and visually displaying the results.
